

**DM204, 2010**  
SCHEDULING, TIMETABLING AND ROUTING

Lecture 12  
**Single Machine Models, Dynamic Programming**

Marco Chiarandini

Department of Mathematics & Computer Science  
University of Southern Denmark

1. Dispatching Rules
2. Single Machine Models

# Organization

- Next week exercise session on Monday or Wednesday?
- Tomorrow: midterm evaluation
- Project to be launched beginning next week
- All elements for tackling it have been given during the past lectures
- Lectures also during the break?
- How the course will continue  
We will look closer into scheduling models and learn:
  - special algorithms
  - application of general methods

- ✓ Problem Introduction
  - ✓ Scheduling classification
  - ✓ Scheduling complexity
  - ✓ RCPSP
- General Methods
  - ✓ Integer Programming
  - ✓ Constraint Programming
  - ✓ Heuristics
    - [Dynamic Programming](#)
    - Branch and Bound
- [Scheduling](#)
  - [Single Machine](#)
  - Parallel Machine and Flow Shop Models
  - Job Shop
  - Resource Constrained Project Scheduling Model
- Timetabling
  - Reservations and Education
  - University Timetabling
  - Crew Scheduling
  - Public Transports
- Vehicle Routing
  - Capacited Models
  - Time Windows models
  - Rich Models

1. Dispatching Rules

2. Single Machine Models

# Dispatching rules

Distinguish **static** and **dynamic** rules.

- Service in random order (SIRO)
- Earliest release date first (ERD=FIFO)
  - tends to min variations in waiting time
- Earliest due date (EDD)
- Minimal slack first (MS)
  - $j^* = \arg \min_j \{ \max(d_j - p_j - t, 0) \}$ .
  - tends to min due date objectives (T,L)

- (Weighted) shortest processing time first (WSPT)
  - $j^* = \arg \max_j \{w_j/p_j\}$ .
  - tends to min  $\sum w_j C_j$  and max work in progress and
- Longest processing time first (LPT)
  - balance work load over parallel machines
- Shortest setup time first (SST)
  - tends to min  $C_{max}$  and max throughput
- Least flexible job first (LFJ)
  - eligibility constraints

- Critical path (CP)
  - first job in the CP
  - tends to min  $C_{max}$
- Largest number of successors (LNS)
- Shortest queue at the next operation (SQNO)
  - tends to min idleness of machines

# Dispatching Rules in Scheduling

	RULE	DATA	OBJECTIVES
Rules Dependent on Release Dates and Due Dates	ERD	$r_j$	Variance in Throughput Times
	EDD	$d_j$	Maximum Lateness
	MS	$d_j$	Maximum Lateness
Rules Dependent on Processing Times	LPT	$p_j$	Load Balancing over Parallel Machines
	SPT	$p_j$	Sum of Completion Times, WIP
	WSPT	$p_j, w_j$	Weighted Sum of Completion Times, WIP
	CP	$p_j, prec$	Makespan
	LNS	$p_j, prec$	Makespan
Miscellaneous	SIRO	-	Ease of Implementation
	SST	$s_{jk}$	Makespan and Throughput
	LFJ	$M_j$	Makespan and Throughput
	SQNO	-	Machine Idleness

When dispatching rules are optimal?

	RULE	DATA	ENVIRONMENT
1	SIRO	—	—
2	ERD	$r_j$	$1 \mid r_j \mid \text{Var}(\sum(C_j - r_j)/n)$
3	EDD	$d_j$	$1 \parallel L_{\max}$
4	MS	$d_j$	$1 \parallel L_{\max}$
5	SPT	$p_j$	$Pm \parallel \sum C_j; Fm \mid p_{ij} = p_j \mid \sum C_j$
6	WSPT	$w_j, p_j$	$Pm \parallel \sum w_j C_j$
7	LPT	$p_j$	$Pm \parallel C_{\max}$
8	SPT-LPT	$p_j$	$Fm \mid \text{block}, p_{ij} = p_j \mid C_{\max}$
9	CP	$p_j, prec$	$Pm \mid prec \mid C_{\max}$
10	LNS	$p_j, prec$	$Pm \mid prec \mid C_{\max}$
11	SST	$s_{jk}$	$1 \mid s_{jk} \mid C_{\max}$
12	LFJ	$M_j$	$Pm \mid M_j \mid C_{\max}$
13	LAPT	$p_{ij}$	$O2 \parallel C_{\max}$
14	SQ	—	$Pm \parallel \sum C_j$
15	SQNO	—	$Jm \parallel \gamma$

# Composite dispatching rules

Why composite rules?

- Example:  $1 || \sum w_j T_j$ :
  - WSPT, optimal if due dates are zero
  - EDD, optimal if due dates are loose
  - MS, tends to minimize  $T$

► The efficacy of the rules depends on instance **factors**

## Instance characterization

- Job attributes: {weight, processing time, due date, release date}
- Machine attributes: {speed, num. of jobs waiting, num. of jobs eligible}
- Possible instance factors:
  - $1 || \sum w_j T_j$

$$\theta_1 = 1 - \frac{\bar{d}}{C_{max}} \quad (\text{due date tightness})$$

$$\theta_2 = \frac{d_{max} - d_{min}}{C_{max}} \quad (\text{due date range})$$

- $1 | s_{jk} | \sum w_j T_j$

$$(\theta_1, \theta_2 \text{ with estimated } \hat{C}_{max} = \sum_{j=1}^n p_j + n\bar{s})$$

$$\theta_3 = \frac{\bar{s}}{\bar{p}} \quad (\text{set up time severity})$$

- $1 \mid \mid \sum w_j T_j$ , dynamic apparent tardiness cost (ATC)

$$l_j(t) = \frac{w_j}{p_j} \exp\left(-\frac{\max(d_j - p_j - t, 0)}{K\bar{p}}\right)$$

- $1 \mid s_{jk} \mid \sum w_j T_j$ , dynamic apparent tardiness cost with setups (ATCS)

$$l_j(t, l) = \frac{w_j}{p_j} \exp\left(-\frac{\max(d_j - p_j - t, 0)}{K_1\bar{p}}\right) \exp\left(\frac{-s_{jk}}{K_2\bar{s}}\right)$$

after job  $l$  has finished.

1. Dispatching Rules

2. Single Machine Models

# Outlook

$1 \mid \mid \sum w_j C_j$  : weighted shortest processing time first is optimal

$1 \mid \mid \sum_j U_j$  : Moore's algorithm

$1 \mid prec \mid L_{max}$  : Lawler's algorithm, backward dynamic programming in  $O(n^2)$  [Lawler, 1973]

$1 \mid \mid \sum h_j(C_j)$  : dynamic programming in  $O(2^n)$

$1 \mid \mid \sum w_j T_j$  : local search and dynasearch

$1 \mid r_j, (prec) \mid L_{max}$  : branch and bound

$1 \mid s_{jk} \mid C_{max}$  : in the special case, Gilmore and Gomory algorithm optimal in  $O(n^2)$

$1 \mid \mid \sum w_j T_j$  : column generation approaches

Multicriteria

## Single Machine Models:

- $C_{max}$  is sequence independent
- if  $r_j = 0$  and  $h_j$  is monotone non decreasing in  $C_j$  then optimal schedule is nondelay and has no preemption.

$$1 \parallel \sum w_j C_j$$

[Total weighted completion time]

### Theorem

*The weighted shortest processing time first (WSPT) rule is optimal.*

Extensions to  $1 \mid prec \mid \sum w_j C_j$

- in the general case strongly NP-hard
- **chain** precedences:  
process first chain with highest  $\rho$ -factor up to, and included, job with highest  $\rho$ -factor.
- polytime algorithm also for tree and sp-graph precedences

Extensions to  $1 \mid r_j, prmp \mid \sum w_j C_j$

- in the general case strongly NP-hard
- preemptive version of the WSPT if equal weights
- however,  $1 \mid r_j \mid \sum w_j C_j$  is strongly NP-hard

$$1 \parallel \sum_j U_j$$

[Number of tardy jobs]

- [Moore, 1968] algorithm in  $O(n \log n)$ 
  - Add jobs in increasing order of due dates
  - If inclusion of job  $j^*$  results in this job being completed late discard the scheduled job  $k^*$  with the longest processing time
- $1 \parallel \sum_j w_j U_j$  is a knapsack problem hence NP-hard

# Dynamic programming

Procedure based on divide and conquer

**Principle of optimality** the completion of an optimal sequence of decisions must be optimal

- Break down the problem into stages at which the decisions take place
- Find a recurrence relation that takes us backward (forward) from one stage to the previous (next)
- Typical technique: labelling with dominance criteria

(In scheduling, backward procedure feasible only if the makespan is schedule independent, eg, single machine problems without setups, multiple machines problems with identical processing times.)

1 | *prec* |  $h_{max}$ 

- $h_{max} = \max\{h_1(C_1), h_2(C_2), \dots, h_n(C_n)\}$ ,  $h_j$  regular
- special case: 1 | *prec* |  $h_{max}$  [maximum lateness]
- solved by backward dynamic programming in  $O(n^2)$  [Lawler, 1978]

$J$  set of jobs already scheduled;

$J^c$  set of jobs still to schedule;

$J' \subseteq J^c$  set of schedulable jobs

Step 1: Set  $J = \emptyset$ ,  $J^c = \{1, \dots, n\}$  and  $J'$  the set of all jobs with no successor

Step 2: Select  $j^*$  such that  $j^* = \arg \min_{j \in J'} \{h_j (\sum_{k \in J^c} p_k)\}$ ;  
add  $j^*$  to  $J$ ; remove  $j^*$  from  $J^c$ ; update  $J'$ .

Step 3: If  $J^c$  is empty then stop, otherwise go to Step 2.

- For 1 | |  $L_{max}$  Earliest Due Date first
- 1 |  $r_j$  |  $L_{max}$  is instead strongly NP-hard

# 1 || $\sum h_j(C_j)$

- generalization of  $\sum w_j T_j$  hence strongly NP-hard
- (forward) dynamic programming algorithm  $O(2^n)$

$J$  set of jobs already scheduled;

$$V(J) = \sum_{j \in J} h_j(C_j)$$

Step 1: Set  $J = \emptyset$ ,  $V(j) = h_j(p_j)$ ,  $j = 1, \dots, n$

Step 2:  $V(J) = \min_{j \in J} (V(J - \{j\}) + h_j(\sum_{k \in J} p_k))$

Step 3: If  $J = \{1, 2, \dots, n\}$  then  $V(\{1, 2, \dots, n\})$  is optimum, otherwise go to Step 2.

# $1 \parallel \sum h_j(C_j)$

A lot of work done on  $1 \parallel \sum w_j T_j$   
[single-machine total weighted tardiness]

- $1 \parallel \sum T_j$  is hard in ordinary sense, hence admits a pseudo polynomial algorithm (dynamic programming in  $O(n^4 \sum p_j)$ )
- $1 \parallel \sum w_j T_j$  strongly NP-hard (reduction from 3-partition)
  - exact solution via branch and bound feasible up to 40 jobs [Potts and Wassenhove, Oper. Res., 1985]
  - exact solution via time-indexed integer programming formulation used to lower bound in branch and bound solves instances of 100 jobs in 4-9 hours [Pan and Shi, Math. Progm., 2007]
  - dynasearch: results reported for 100 jobs within a 0.005% gap from optimum in less than 3 seconds [Grosso et al., Oper. Res. Lett., 2004]

# 1 || $\sum h_j(C_j)$

## Local search (revisited)

1. search space (solution representation)
2. initial solution
3. neighborhood function
4. evaluation function
5. step function
6. memory states
7. termination predicate

## Speedups Techniques for Efficient Neighborhood Search

- 1) Incremental updates
- 2) Neighborhood pruning

# 1 || $\sum h_j(C_j)$

## Neighborhood updates and pruning

- Interchange neigh.: size  $\binom{n}{2}$  and  $O(|i - j|)$  evaluation each
  - first-improvement:  $\pi_j, \pi_k$ 
    - $\rho_{\pi_j} \leq \rho_{\pi_k}$  for improvements,  $w_j T_j + w_k T_k$  must decrease because jobs in  $\pi_j, \dots, \pi_k$  can only increase their tardiness.
    - $\rho_{\pi_j} \geq \rho_{\pi_k}$  possible use of auxiliary data structure to speed up the computation
  - best-improvement:  $\pi_j, \pi_k$ 
    - $\rho_{\pi_j} \leq \rho_{\pi_k}$  for improvements,  $w_j T_j + w_k T_k$  must decrease at least as the best interchange found so far because jobs in  $\pi_j, \dots, \pi_k$  can only increase their tardiness.
    - $\rho_{\pi_j} \geq \rho_{\pi_k}$  possible use of auxiliary data structure to speed up the computation
- Swap: size  $n - 1$  and  $O(1)$  evaluation each
- Insert: size  $(n - 1)^2$  and  $O(|i - j|)$  evaluation each  
 But possible to speed up with systematic examination by means of swaps: an interchange is equivalent to  $|i - j|$  swaps hence overall examination takes  $O(n^2)$

## Dynasearch

- two interchanges  $\delta_{jk}$  and  $\delta_{lm}$  are **independent** if  $\max\{j, k\} < \min\{l, m\}$  or  $\min\{l, k\} > \max\{l, m\}$ ;
- the dynasearch neighborhood is obtained by a series of independent interchanges;
- it has size  $2^{n-1} - 1$ ;
- but a best move can be found in  $O(n^3)$  searched by dynamic programming;
- it yields in average better results than the interchange neighborhood alone.

**Table 1 Data for the Problem Instance**

Job $j$	1	2	3	4	5	6
Processing time $p_j$	3	1	1	5	1	5
Weight $w_j$	3	5	1	1	4	4
Due date $d_j$	1	5	3	1	3	1

**Table 2 Swaps Made by Best-Improve Descent**

Iteration	Current Sequence	Total Weighted Tardiness
	1 2 3 4 5 6	109
1	1 2 3 5 4 6	90
2	1 2 3 5 6 4	75
3	5 2 3 1 6 4	70

**Table 3 Dynasearch Swaps**

Iteration	Current Sequence	Total Weighted Tardiness
	1 2 3 4 5 6	109
1	1 3 2 5 4 6	89
2	1 5 2 3 6 4	68
3	5 1 2 3 6 4	67

- state  $(k, \pi)$
- $\pi_k$  is the partial sequence at state  $(k, \pi)$  that has  $\min \sum wT$
- $\pi_k$  is obtained from state  $(i, \pi)$

$$\begin{cases} \text{appending job } \pi(k) \text{ after } \pi(i) & i = k - 1 \\ \text{appending job } \pi(k) \text{ and interchanging } \pi(i + 1) \text{ and } \pi(k) & 0 \leq i < k - 1 \end{cases}$$

- $F(\pi_0) = 0; \quad F(\pi_1) = w_{\pi(1)} (p_{\pi(1)} - d_{\pi(1)})^+;$

$$F(\pi_k) = \min \begin{cases} F(\pi_{k-1}) + w_{\pi(k)} (C_{\pi(k)} - d_{\pi(k)})^+, \\ \min_{1 \leq i < k-1} \{ F(\pi_i) + w_{\pi(k)} (C_{\pi(i)} + p_{\pi(k)} - d_{\pi(k)})^+ + \\ \quad + \sum_{j=i+2}^{k-1} w_{\pi(j)} (C_{\pi(j)} + p_{\pi(k)} - p_{\pi(i+1)} - d_{\pi(j)})^+ + \\ \quad + w_{\pi(i+1)} (C_{\pi(k)} - d_{\pi(i+1)})^+ \} \end{cases}$$

- The best choice is computed by recursion in  $O(n^3)$  and the optimal series of interchanges for  $F(\pi_n)$  is found by backtrack.
- Local search with dynasearch neighborhood starts from an initial sequence, generated by ATC, and at each iteration applies the best dynasearch move, until no improvement is possible (that is,  $F(\pi_n^t) = F(\pi_n^{(t-1)})$ , for iteration  $t$ ).
- Speedups:
  - pruning with considerations on  $p_{\pi(k)}$  and  $p_{\pi(i+1)}$
  - maintainig a string of late, no late jobs
  - $h_t$  largest index s.t.  $\pi^{(t-1)}(k) = \pi^{(t-2)}(k)$  for  $k = 1, \dots, h_t$  then  $F(\pi_k^{(t-1)}) = F(\pi_k^{(t-2)})$  for  $k = 1, \dots, h_t$  and at iter  $t$  no need to consider  $i < h_t$ .

Dynasearch, refinements:

- [Grosso et al. 2004] add insertion moves to interchanges.
- [Ergun and Orlin 2006] show that dynasearch neighborhood can be searched in  $O(n^2)$ .

## Performance:

- exact solution via branch and bound feasible up to 40 jobs [Potts and Wassenhove, Oper. Res., 1985]
- exact solution via time-indexed integer programming formulation used to lower bound in branch and bound solves instances of 100 jobs in 4-9 hours [Pan and Shi, Math. Progm., 2007]
- dynasearch: results reported for 100 jobs within a 0.005% gap from optimum in less than 3 seconds [Grosso et al., Oper. Res. Lett., 2004]

1 ||  $\sum w_j C_j$  : weighted shortest processing time first is optimal
