

## Section 1.6: A Greedy Algorithm

A natural greedy choice would be to „pay“ as little as possible for each additional covered element:

### Alg 1.2 for Set Cover: Greedy

$I \leftarrow \emptyset$

For  $j \leftarrow 1$  to  $m$

$\hat{S}_j \leftarrow S_j$  (uncovered part of  $S_j$ )

While  $\{S_j \mid j \in I\}$  is not a set cover

$l \leftarrow \arg \min_{j: \hat{S}_j \neq \emptyset} \frac{w_j}{|\hat{S}_j|}$  ( $S_l$ : set with smallest cost per uncovered element)

$I \leftarrow I \cup \{l\}$

For  $j \leftarrow 1$  to  $m$

$\hat{S}_j \leftarrow \hat{S}_j - S_l$

The greedy alg. is an  $H_n$ -approx. alg

Recall:  $H_n = 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n} \approx \ln(n)$

It is „likely“ that no significantly better approx. ratio can be obtained:

Thm 1.13 :

Approx. factor  $\frac{\ln n}{c}$ ,  $c > 1$ , for unweighted Set Cover  
 $\Rightarrow n^{O(\log \log n)}$ -approx alg. for NPC

Ex:

$$\frac{w_1}{|S_1|} = \frac{12}{3} = 4$$

$$\frac{w_2}{|S_2|} = \frac{15}{3} = 5$$

$$\frac{w_3}{|S_3|} = \frac{12}{4} = 3$$

$$\frac{w_4}{|S_4|} = \frac{4}{2} = 2 \leftarrow \text{price per element in first iteration}$$

Pick  $S_4$

$$\frac{w_1}{|\hat{S}_1|} = \frac{12}{2} = 6$$

$$\frac{w_2}{|\hat{S}_2|} = \frac{15}{3} = 5$$

$$\frac{w_3}{|\hat{S}_3|} = \frac{12}{3} = 4 \leftarrow \text{price per element in second it.}$$

Pick  $S_3$

$$\frac{w_1}{|\hat{S}_1|} = \frac{12}{1} = 12 \leftarrow \text{price per element in third it.}$$

$$\frac{w_2}{|\hat{S}_2|} = \frac{15}{1} = 15$$

Pick  $S_1$

$$\begin{aligned}
 \text{Greedy} &= 28 \\
 &= w_4 + w_3 + w_1 \\
 &= 4 + 12 + 12 \\
 &= 2 + 2 + 4 + 4 + 4 + 12 \\
 &= \sum_{i=1}^6 \text{price}(e_i)
 \end{aligned}$$

$$\begin{aligned}
 \text{OPT} &= 24 \\
 &= w_3 + w_1 \\
 &= 12 + 12 \\
 &= 4 + 4 + 4 + 4 + 6 + 6
 \end{aligned}$$

We will now use this ex. to illustrate the proof of Thm 1.11 stating that Greedy is an  $H_n$ -approx. alg. :

$H_6$  - approximation:

$$(H_6 = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} = \frac{147}{60} < 2.5)$$

$$OPT \geq 6 \cdot \text{price}(e_1)$$

$$OPT \geq 6 \cdot \text{price}(e_2)$$

since  $S_4$  gives the best average weight per element.

$S_4$  cannot cover any of the elements  $e_3, e_4, e_5, e_6$ . Thus, the average weight of these elements cannot be lower than  $\text{price}(e_3)$ , even for OPT:

$$OPT \geq 4 \cdot \text{price}(e_3)$$

$$OPT \geq 4 \cdot \text{price}(e_4)$$

$$OPT \geq 4 \cdot \text{price}(e_5)$$

Similarly:

$$OPT \geq \text{price}(e_6)$$

$$\text{OPT} \geq 6 \cdot \text{price}(e_1) \quad \Leftrightarrow \quad \text{price}(e_1) \leq \frac{\text{OPT}}{6}$$

$$\text{OPT} \geq 6 \cdot \text{price}(e_2) \quad \Leftrightarrow \quad \text{price}(e_2) \leq \frac{\text{OPT}}{6}$$

$$\text{OPT} \geq 4 \cdot \text{price}(e_3) \quad \Leftrightarrow \quad \text{price}(e_3) \leq \frac{\text{OPT}}{4}$$

$$\text{OPT} \geq 4 \cdot \text{price}(e_4) \quad \Leftrightarrow \quad \text{price}(e_4) \leq \frac{\text{OPT}}{4}$$

$$\text{OPT} \geq 4 \cdot \text{price}(e_5) \quad \Leftrightarrow \quad \text{price}(e_5) \leq \frac{\text{OPT}}{4}$$

$$\text{OPT} \geq \text{price}(e_6) \quad \Leftrightarrow \quad \text{price}(e_6) \leq \text{OPT}$$

$$\text{Greedy} = \sum_{i=1}^6 \text{price}(e_i)$$

$$\leq \frac{\text{OPT}}{6} + \frac{\text{OPT}}{6} + \frac{\text{OPT}}{4} + \frac{\text{OPT}}{4} + \frac{\text{OPT}}{4} + \frac{\text{OPT}}{1}$$

$$\leq \frac{\text{OPT}}{6} + \frac{\text{OPT}}{5} + \frac{\text{OPT}}{4} + \frac{\text{OPT}}{3} + \frac{\text{OPT}}{2} + \frac{\text{OPT}}{1}$$

$$= H_6 \cdot \text{OPT}$$

## Thm 1.11

Alg. 1.2 is an  $H_n$ -approx. alg. for Set Cover

Proof:

$n_k$ : # uncovered elements at the beginning of the  $k$ 'th iteration

Above ex.:  $n_1=6, n_2=4, n_3=1, n_4=0$

$$n_1 - n_2 = 2, n_2 - n_3 = 3, n_3 - n_4 = 1$$

Any algorithm, including OPT, has to cover these  $n_k$  elements using only sets in  $\mathcal{S} - \{S_j \mid j \in I\}$ , since none of them are contained in  $\{S_j \mid j \in I\}$ .

Hence, there must be at least one element with a price of at most  $OPT/n_k$ . Otherwise, OPT would not be able to cover the  $n_k$  elements (and certainly not all  $n$  elements) at a cost of only OPT.

Hence, the  $n_k - n_{k+1}$  elements covered in iteration  $k$  cost at most  $(n_k - n_{k+1}) OPT/n_k$  in total.

Thus, the cost of the set cover produced by the greedy alg. is

$$\begin{aligned}
 \sum_{j \in I} w_j &\leq \sum_{k=1}^r \frac{n_k - n_{k+1}}{n_k} \text{OPT} \\
 &= \text{OPT} \sum_{k=1}^r (n_k - n_{k+1}) \cdot \frac{1}{n_k} \\
 &\leq \text{OPT} \underbrace{\sum_{k=1}^r \left( \frac{1}{n_k} + \frac{1}{n_{k+1}} + \dots + \frac{1}{n_{k+1}+1} \right)}_{n_k - n_{k+1} \text{ terms that are each } \geq \frac{1}{n_k}} \\
 &= \text{OPT} \sum_{s=1}^n \frac{1}{s} \\
 &= \text{OPT} \cdot H_n \quad \square
 \end{aligned}$$

Let  $H_g = \max \{ |S_i| \mid S_i \in \mathcal{S} \}$ .

Thm 1.12

Alg. 1.2 is an  $H_g$ -approx. alg. for Set Cover

Proof: By Dual Fitting:

Consider the dual  $D$  of the LP for Set Cover.  
We will construct

- an infeasible solution  $\vec{y}$  and
- a feasible solution  $\vec{y}'$

such that

- $\sum_{i=1}^n y_i = \sum_{j \in I} w_j$  (obtained, if  $y_i = \text{price}(e_i)$ )
- $y'_i = \frac{1}{H_g} \cdot y_i$

Then,

$$\sum_{j \in I} w_j = \sum_{i=1}^n y_i = H_g \sum_{i=1}^n y'_i \leq H_g Z_D^* \leq H_g \cdot \text{OPT},$$

proving the claimed approximation factor.  $\square$

For  $1 \leq i \leq n$ , let  $y_i = \text{price}(e_i)$ . Then,  $\sum_{1 \leq i \leq n} y_i = \sum_{j \in I} w_j$ .

Hence, we just need to show that  $\vec{y}$  is feasible:

Consider an arbitrary set  $S_j$ .

Let  $a_k$  be #uncovered elements in  $S_j$  at the beginning of the  $k$ 'th iteration.

Let  $S_p$  be the set chosen by Greedy in the  $k$ 'th iteration.

$S_p$  covers  $a_k - a_{k+1}$  previously uncovered elements in  $S_j$

The price per elem. in  $S_j$  covered in the  $k$ 'th it. is

$$\frac{w_p}{|\hat{S}_p|} \leq \frac{w_j}{|\hat{S}_j|} \leq \frac{w_j}{a_k}$$

since otherwise  $S_j$  would be a more greedy choice.  $\frac{1}{4}$

Thus,

$$\begin{aligned} \sum_{e_i \in S_j} y_i &\leq \underbrace{\sum_{k=1}^r (a_k - a_{k+1}) \frac{w_j}{a_k}}_{\text{Total \# items} = |S_j|, \text{ since } a_1 = |S_j| \text{ and } a_{r+1} = 0} \\ &\leq w_j \sum_{i=1}^{|S_j|} \frac{1}{i}, \text{ by the same arguments as in} \\ &\quad \text{the proof of Thm 1.12.} \\ &\leq w_j \sum_{i=1}^g \frac{1}{i} \\ &= w_j \cdot H_g \end{aligned}$$

Hence,

$$\sum_{e_i \in S_j} y_i' = \frac{1}{H_g} \sum_{e_i \in S_j} y_i \leq w_j$$

□

Compare the proof of Thm 1.12 (dual fitting) to the proof of Thm 1.11:

- Simpler: Compare prices to  $w_j$  instead of OPT
- Stronger result:  $H_g$  instead of  $H_n$   
(could also have been obtained with the technique of the proof of Thm 1.11)

Ex from before:

$$g = 4 \Rightarrow \frac{1}{g} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} = \frac{25}{12} < 2.1$$

$$y_1 = y_2 = 2$$

$$y_3 = y_4 = y_5 = 4$$

$$y_6 = 12$$

$$y_1' = y_2' = \frac{24}{25}$$

$$y_3' = y_4' = y_5' = \frac{48}{25}$$

$$y_6' = \frac{144}{25}$$

Dual constraints:

$$y_1' + y_3' + y_6' \leq 12$$

$$\frac{24}{25} + \frac{48}{25} + \frac{144}{25} = \frac{216}{25} < 12$$

$$y_4' + y_5' + y_6' \leq 15$$

$$\frac{48}{25} + \frac{48}{25} + \frac{144}{25} = \frac{240}{25} < 15$$

$$y_2' + y_3' + y_4' + y_5' \leq 12$$

$$\frac{24}{25} + \frac{48}{25} + \frac{48}{25} + \frac{48}{25} = \frac{168}{25} < 12$$

$$y_1' + y_2' \leq 4$$

$$\frac{24}{25} + \frac{24}{25} < 4$$

Is the upper bound of  $H_n$  tight?

If it is, the matching lower bound must come from an instance with

- one set containing all elements  
(follows from the upper bound of  $H_2$ )
- only one additional element covered in each it.  
(otherwise, some of the terms in  $\frac{1}{n} + \frac{1}{n-1} + \dots + 1$  would be replaced by smaller terms.)

Ex:

# Summary

## Greedy

$H_n$ -approx.:

$$\text{price}(e_i) \leq \frac{\text{OPT}}{n-i}, \quad i = 0, 1, \dots, n-1$$

$H_g$ -approx: ( $g$ : size of largest set)

Dual fitting:

$y'_i \leftarrow \frac{\text{price}(e_i)}{H_g}$  is a feasible sol. to dual
